

Author/Title Journal/Year	Type of Study	Outcomes Studied	Patient Characteristics	Results	HCFA Comments
Al-Momen AK, Huraib S, Mitwalli A, et al / Intravenous iron saccharate in hemodialysis patients receiving r- HuEPO / Saudi Journal of Kidney Diseases and Transplantation / 1994	Cohort study	Effects of erythropoietin therapy (EPO) and intravenous (IV) iron (Fe) saccharate were assessed using hemoglobin (Hb), hematocrit (Hct), serum iron, serum ferritin (SF), and total iron binding capacity (TIBC) as primary endpoints.	109 hemodialysis (HD) patients were enrolled into the study. All were treated with EPO therapy for a minimum of 8 weeks. Patients who were iron deficient were given 100 units/kg of EPO. Patients who were not iron deficient were given 50 units/kg of EPO. Patients that were excluded from the study had active bleeding, hemoysis, inflammation, infection, or malignancy. Patients were divided into 2 treatment groups. Group 1 (n=58) received high dose IV Fe (500mg). Group 2 received low dose IV Fe (100mg).	Group 1 had 42 iron deficient patients and 16 non-iron deficient patients. Group 2 had 22 iron deficient patients and 29 non-iron deficient patients. All patients from both groups showed statistically significant increase in Hct, Hb, TIBC, SF levels at the 4th week of IV Fe administration. EPO doses for the iron deficient patients were also lowered to 50 units/kg. Group 1 experienced adverse effects in 9 patients. None were reported in Group 2.	Study provided data on the dose-related effectiveness of IV Fe saccharate. There was no description of how samples from groups were divided; lack of randomization may introduce selection bias. Furthermore, analysis made no mention of distinctions made between iron deficient and non-iron deficient. Authors stated patients with functional iron deficiency were excluded, but they did not elaborate on how these No comparisons were made between IV Fe and oral iron.
Bailie G, Johnson C, Mason N / Parenteral iron use in the management of anemia in end- stage renal disease patients / American Journal of Kidney Diseases / 2000	Overview	Not a clinical trial.	Not a clinical trial.	Not a clinical trial.	Article provided a comparative review of the available literature on safety, toxicity, and clinical effectiveness of three IV Fe agents: iron dextran, iron

					sucrose, a gluconate.
Domrongkitchaiporn, S Jirakranont B, Aramasnkul K, Ungkanont A, Bunyaratvej A / Indices of iron status in continuous ambulatory peritoneal dialysis patients / American Journal of Kidney Diseases / 1999	Cohort study	<p>Complete blood count (CBC), reticulocyte HgB content, SF, TSAT, C-reactive protein, and intact parathyroid hormone levels were measured.</p> <p>Patients with a sustained increase in Hb content of greater than 1 gm/dL within 3 months after Fe infusion were defined as being Fe deficient. Those who did not were defined as nonresponders.</p>	<p>23 CAPD patients were eligible for the study. 2 patients were excluded (death from pneumonia &amp; discontinuation of EPO).</p> <p>No change in EPO dose was allowed. Patients were given IV Fe sucrose.</p> <p>Inclusion criteria: stable CAPD for at least 3 months, receiving constant doses of EPO and oral Fe for at least 3 months, Hgb &lt; 10 gm/dl, no hematological disorders other than anemia, no iv fe therapy for at least 1 month before study, no liver dysfunction of systemic illness that affects response to epo.</p> <p>Exclusion criteria: significant bleeding or blood transfusions; hospitalization, surgery, of infection requiring antibiotics; receiving other</p>	<p>21 patients completed the study. 15 patients (71.4%) responded to treatment and were considered Fe deficient.</p> <p>No adverse reactions developed during treatment.</p> <p>9 of 13 (69%) patients with presence of bone marrow-stainable iron still responded to therapy.</p> <p>The authors calculate sensitivity/specificity values for the iron status indicators based on their ability to predict response to treatment</p>	<p>Study is m designed t assess the sensitivity specificity indices use measure in status. It i difficult to extrapolate conclusion regarding effectiveness IV iron suc</p>

			forms of Fe supplementation; change in EPO dose; adverse reaction to IV Fe therapy; or poor compliance.		
Faich G, Strobos J / Sodium ferric gluconate complex in sucrose: safer intravenous iron therapy than iron dextrans / American Journal of Kidney Diseases / 1999	Retrospective analysis of market data	Safety of IV Fe gluconate complex (Ferrlecit) was compared to IV Fe dextran using adverse reaction rates and case-fatality rates .	Adverse event reports from the World Health Organization (WHO) were used to assess adverse reactions. Manufacturers of the iron products were contacted to estimate the number of units sold annually.	-- 3.3 allergy episodes per million doses sold for sodium ferric gluconate. -- 8.7 allergy episodes per millions doses sold for iron dextran.  IV Fe gluconate had a substantially lower case fatality rate compared to Fe dextran (0 vs. 15.8%).	While the absolute number of episodes reported suggests a distinction, a portion of the number of administered difference miniscule (0.000003 vs. 0.0000087). The study does not address clinical effectiveness of one product compared to the other.
Frankenfield D, Johnson C, Wish J, Rocco M, Madore F, Owen W / Anemia management of adult hemodialysis patients in the US: results from the 1997 ESRD Core Indicators Project / Kidney International / 2000	Epidemiological study	Hct, TSAT, SF, weekly EPO dose, serum albumin and iron prescription practices were assessed.	Analysis was conducted on the medical records of a random sampling of Medicare-eligible ESRD patients who were receiving in-center HD on 12/31/96. Patients who were not on EPO were excluded from analysis. Of a sample of 7292 patients, 4991 were included in the final analysis.	The mean Hct for the entire sample was 32.6% +/- 3.5%. 72% of patients had a Hct > 30%, while 42% had Hct between 33 - 36%. Mean SF level was 386 ng/ml +/- 422 ng/ml. 79% had levels greater than or equal to 100 ng/ml. 77% of patients were prescribed iron (in some form) at least once in the 3 month study. Only 54% patient were prescribed IV Fe.	Study highlights current standard hematological indicators for anemia within the Medicare ESRD population. The authors point out the need for better iron prescription practices, especially for IV Fe therapy.
Hussain R, Chishti S, Naqvi S / Experience	Cohort study	Hb, Hct, TSAT, EPO dosage,	20 HD patients were enrolled	Group 1 Hb init. 7.8	2 Study provides some evidence

<p>of iron saccharate supplementation in haemodialysis patients treated with erythropoietin / Nephrology / 1998</p>		<p>and SF levels were monitored and compared as iron-replete patients underwent either oral iron therapy or IV Fe saccharate therapy for 3 months.</p>	<p>into the study. Patients had Hb &lt; 8.5 g/dl, normal folate and b12 level, sf between 200 and 800 ng/ml, and tsat &gt; 30%.</p> <p>Patients were split into 2 groups: Group 1 (n=10) were on IV Fe saccharate (100mg), Group 2 (n=10) were given oral Fe (60mg) 3 times a day.</p> <p>EPO therapy was also commenced on both groups. Dosage was adjusted according to Hb.</p>	<p>8.0 end 11.6 10.5 p-val &lt;0.001 &lt;0.001 SF init. 386 446 end 671 367 p-val &lt;0.05 =0.50 Target Hb (11-12 G/dl) was achieved in all Group 1 patients except one. Only 5 patients achieved target Hb levels in Group 2. EPO dose was increase in 1 patients from Group 1 and 6 patients in Group 2.</p>	<p>that iron-r patients tr with IV Fe saccharate a better response t therapy compared those on o iron therap sample siz in each gro quite smal addition, p were not randomize between th treatment groups. Although t study asse the safety Fe sucrose patients w documente dextran sensitivity,																				

<p>Journal of Kidney Diseases / 2000</p>		<p>outcome measures include increases in TSAT, SF, and serum Fe-binding capacity.</p> <p>All patients were included in an intent-to-treat analysis.</p>	<p>Fe dextran and an Hgb level &lt; 11.0 g/dl. all patients who met the above criteria were included.</p> <p>Patients were assigned to two treatment groups based on severity of their reactions to IV Fe dextran: Group A (n=16) had history of mild reactions, Group B (n=7) had history of severe reactions. Eligibility for Group B also required evidence of Fe deficiency ( TSAT &lt; 20% and sf &lt; 300 ng/ml). all patients were given iv fe sucros</p> <p>e. Patients were excluded for the following reasons: inflammatory disease, causes of anemia other than ESRD or Fe deficiency, asthma, pregnancy, bacterial or viral infection, severe cardiac, hepatic, or psychiatric disorder, need for transfusion, surgery or transplantation durina studv</p>	<p>to Fe therapy).</p> <p>A 223 doses of Fe sucrose were administered during the study. There were no serious adverse reactions recorded, no episodes of anaphylaxis, no patient withdrawal, and no drug discontinuation caused by drug-related adverse events. 3 mild adverse events possibly related to the IV Fe sucrose were observed in 2 patients. All efficacy outcomes showed a significant degree of improvement after therapy. Increase in Hgb levels was first significant at day 15 after 6 doses of the drug. EPO doses were stable prior to study and declined slightly during the study.</p>	<p>gives no indication the adverse reaction rate general sa data of Fe sucrose in general population also does n compare I sucrose's s profiles wit of iron dex the genera population</p>

			period, and evidence of Fe overload.		
Vychytil A, Haag-Weber M / Iron status and iron supplementation in peritoneal dialysis patients / Kidney International / 1999	Review	Not a clinical trial.	Not a clinical trial.	Not a clinical trial.	This article provides a review of the available literature on Fe use in peritoneal dialysis patients. The author reviews the findings of their own studies. However, there is no detailed description of the protocols or methodology used to analyze the results, making a thorough review and critique of the clinical information difficult.
